**Abstract.** The purpose of this paper is to introduce weakly  $\beta$ - $R_0$  spaces,  $\beta$ -US spaces and to obtain their basic properties. It is shown that weakly  $\beta$ - $R_0$  and  $\beta$ -US spaces are preserved under pre- $\beta$ -closed injection and pre- $\beta$ -closed bijection respectively.

**Keywords:** weakly semi- $R_0$  spaces, weakly  $\beta$ - $R_0$  spaces,  $\beta$ -US spaces

**MSC 2000 classification:** 54C10, 54D10

## 1 Introduction and preliminaries

In 1986, Monsef et al. [2] defined and studied  $\beta$ -closure of a set in topological spaces. In this paper, using  $\beta$ -closure, we introduce weakly  $\beta$ - $R_0$  spaces for non trivial topology,  $\beta$ -US spaces and obtained preservation theorems for weakly  $\beta$ - $R_0$  spaces and  $\beta$ -US spaces. Several characterizations and fundamental properties are obtained. Throughout the present paper,  $X$  and  $Y$  always mean topological spaces on which no separation axiom is assumed unless explicitly stated.

Let  $A$  be a subset of a space  $X$ . The closure of  $A$  and interior of  $A$  are denoted by  $\text{Cl}(A)$  and  $\text{Int}(A)$  respectively.

Here we recall the following definitions, which will be used often throughout the paper.

**1 Definition.** A subset  $A$  of a topological space  $X$  is said to be  $\beta$ -open [1] (resp. semi-open [7],  $\alpha$ -open [11]) if  $A \subseteq \text{Cl}(\text{Int}(\text{Cl}(A)))$  (resp.  $A \subseteq \text{Cl}(\text{Int}(A))$ ,  $A \subseteq \text{Int}(\text{Cl}(\text{Int}(A)))$ ). The complement of a  $\beta$ -open (resp. semi-open) set is said to be  $\beta$ -closed [1] (resp. semi-closed [5]) and  $\beta$ -closure [2] (resp. semi-closure [5]) of a set  $A$ , denoted by  $\beta \text{Cl}(A)$  (resp.  $\text{SCl}(A)$ ), is the intersection of all  $\beta$ -closed (resp. semi-closed) sets containing  $A$ .  $A$  is said to be  $\beta$ -clopen [13] if it is  $\beta$ -open as well as  $\beta$ -closed.

## 2 Weakly $\beta$ - $R_0$ spaces

**2 Definition.** A topological space  $X$  is said to be *semi- $R_0$*  [8] if and only if for each  $x \in X$ ,  $\text{SCl}(\{x\}) \subseteq G$ , where  $G$  is an open subset of  $X$ .

**3 Definition.** A topological space  $X$  is said to be *weakly semi- $R_0$*  [4] if and only if  $\cap \text{SCl}(\{x\}) : x \in X = \emptyset$ .

**4 Definition.** A topological space  $X$  is said to be *weakly  $\beta$ - $R_0$*  if and only if  $\cap \beta \text{Cl}(\{x\}) : x \in X = \emptyset$ .

**5 Theorem.** *Every weakly semi- $R_0$  space is weakly  $\beta$ - $R_0$ .*

PROOF. The proof is obvious in view of the fact that

$$\cap \{\beta \text{Cl}(\{x\}) : x \in X\} \subset \cap \{\text{SCl}(\{x\}) : x \in X\}.$$

□ QED

The converse of the above theorem is not true as can be seen from the following example:

**6 Example.** Let  $X = \{a, b, c\}$ ,  $T = \{\emptyset, X, \{a, b\}\}$ . It is evident that

$$\cap \{\beta \text{Cl}(\{x\}) : x \in X\} = \emptyset \text{ but } \cap \{\text{SCl}(\{x\}) : x \in X\} = \{c\} \neq \emptyset.$$

**7 Theorem.** *If a space  $X$  is weakly  $\beta$ - $R_0$  then for every space  $Y$ , the product space  $X \times Y$  is weakly  $\beta$ - $R_0$ .*

PROOF. Using [2, Theorem 2.10], we have

$$\begin{aligned} \cap \{\beta \text{Cl}(\{x, y\}) : (x, y) \in X \times Y\} \\ \subseteq \cap \{\beta \text{Cl}(\{x\}) \times \beta \text{Cl}(\{y\}) : (x, y) \in X \times Y\} \\ = \cap \{\beta \text{Cl}(\{x\}) : x \in X\} \times \cap \{\beta \text{Cl}(\{y\}) : y \in Y\} \subseteq \emptyset \times Y = \emptyset. \end{aligned}$$

□ QED

**8 Definition.** A function  $f: X \rightarrow Y$  is said to be *pre- $\beta$ -closed* [9] if the image of each  $\beta$ -closed subset of  $X$  is  $\beta$ -closed in  $Y$ .

**9 Theorem.** *Let  $f: X \rightarrow Y$  be a pre- $\beta$ -closed injective function. If  $X$  is weakly  $\beta$ - $R_0$ , then so is  $Y$ .*

PROOF. Using [9, Theorem 3.3 (ii)], we have

$$\begin{aligned} \cap \{\beta \text{Cl}(\{y\}) : y \in Y\} \subseteq \cap \{\beta \text{Cl}(\{f(x)\}) : x \in X\} \\ \subseteq f(\cap \{\beta \text{Cl}(\{x\}) : x \in X\}) = f(\emptyset) = \emptyset. \end{aligned}$$

□ QED

**10 Definition.** Let  $(X, T)$  be a topological space and let  $x \in X$ . The  $\beta$ -Kernel of  $x$  is denoted and defined by

$$\beta\text{-ker}(x) = \cap \{U : U \text{ is } \beta\text{-open in } X \text{ and } x \in U\}.$$

**11 Theorem.** A topological space  $X$  is weakly  $\beta$ - $R_0$  if and only if  $\beta\text{-ker}(x) \neq X$  for each  $x \in X$ .

PROOF. Let  $x_0$  be a point of  $X$  such that  $\beta\text{-ker}(x_0) = X$ . This means that  $x_0$  does not belong to any proper  $\beta$ -open subset of  $X$ . Therefore  $x_0$  belongs to every proper  $\beta$ -closed subset of  $X$ . Hence  $x_0$  belongs to the  $\beta$ -closure of every singleton. Therefore  $x_0 \in \cap \{\beta\text{Cl}(\{x\}) : x \in X\} = \emptyset$ , as by assumption  $X$  is weakly  $\beta$ - $R_0$ . This is a contradiction.

Conversely, assume that  $\beta\text{-ker}(x) \neq X$  for each  $x \in X$ . If there is a point  $x_0$  in  $X$  such that  $x_0 \in \beta\text{Cl}(\{x\})$  then, every  $\beta$ -open set containing  $x_0$  must contain every point of  $X$ . Therefore, the unique  $\beta$ -open set containing  $x_0$  is  $X$ . Hence  $\beta\text{-ker}(x_0) = X$ , which is a contradiction. Thus  $X$  is weakly  $\beta$ - $R_0$ .  $\square$

### 3 $\beta$ -US-spaces

The concept of US-space was introduced by Slepian [15] and was further studied by Cullen [6], Murudeshwar, Nainpally [10] and Wilansky [16]. A space  $X$  is said to be a US-space if every sequence in  $X$  converges to a unique point. In this section, we introduce a weaker concept namely the concept of  $\beta$ -US spaces by making use of  $\beta$ -open sets.

**12 Definition.** A sequence  $\langle x_n \rangle$  is said to *s-converge* [3] to a point of  $x$  if  $\langle x_n \rangle$  is eventually in every semi-open set containing  $x$ .

**13 Definition.** A sequence  $\langle x_n \rangle$  is said to  *$\beta$ -converge* to a point  $x$  if  $\langle x_n \rangle$  is eventually in every  $\beta$ -open set containing  $x$ .

**14 Definition.** A space  $X$  is said to be *semi-US* [3] if every sequence in  $X$  s-converges to a unique point. Every US-space is semi-US but not conversely [3, Example 1.5].

**15 Definition.** A space  $X$  is said to be  $\beta$ -US if every sequence in  $X$   $\beta$ -converges to a unique point.

Clearly, every semi-US space is  $\beta$ -US but not conversely as can be seen from the following example:

**16 Example.** Let  $X = \{a, b, c, d\}$  and let  $T = \{\emptyset, X, \{a, b, c\}, \{b, c, d\}, \{b, c\}\}$  then  $(X, T)$  is  $\beta$ -US space but not semi-US space, not even  $T_1$ .

**17 Definition.** A space  $X$  is said to be  $\beta$ - $T_1$  (respectively,  $\beta$ - $T_2$ ) [9] if for any two distinct points  $x$  and  $y$  of  $X$ , there exist  $\beta$ -open sets  $U$  and  $V$  such that

$x \in U$  and  $y \notin U$ ,  $y \in V$  and  $x \notin V$  (resp.  $x \in U, y \in V$  and  $U \cap V = \emptyset$ ).

**18 Theorem.** *Every  $\beta$ -US space is  $\beta$ - $T_1$ .*

PROOF. Let  $X$  be  $\beta$ -US. Let  $x$  and  $y$  be two distinct points of  $X$ . Consider the sequence  $\langle x_n \rangle$  where  $x_n = x$  for every  $n$ . Clearly  $\langle x_n \rangle$   $\beta$ -converges to  $x$ . Also, since  $x \neq y$  and  $X$  is  $\beta$ -US,  $\langle x_n \rangle$  cannot  $\beta$ -converge to  $y$ . That is, there exists a  $\beta$ -open set  $V$  containing  $y$  but not  $x$ . Similarly if we consider the sequence  $\langle y_n \rangle$  where  $y_n = y$  for all  $n$  and proceeding as before, we get a  $\beta$ -open set  $U$  containing  $x$  but not  $y$ . Thus  $X$  is  $\beta$ - $T_1$ .  $\square$

The converse of the above theorem need not be true as can be seen from the following example:

**19 Example.** Let  $X$  be a countably infinite set and  $T$  be the cofinite topology on  $X$ . Then  $(X, T)$  is  $T_1$ , hence  $\beta$ - $T_1$  but not  $\beta$ -US since the every sequence of distinct points of  $X$  converges to more than one point.

**20 Theorem.** *Every  $\beta$ - $T_2$  space is  $\beta$ -US.*

PROOF. Let  $X$  be  $\beta$ - $T_2$  and let  $\langle x_n \rangle$  be a sequence in  $X$ . If possible, suppose that  $\langle x_n \rangle$   $\beta$ -converges to two points  $x$  and  $y$ . That is,  $\langle x_n \rangle$  is eventually in every  $\beta$ -open set containing  $x$  and also in every  $\beta$ -open set containing  $y$ . This is not possible since  $X$  is  $\beta$ - $T_2$ . Thus  $x = y$ .  $\square$

Converse of the above theorem need not be true as can be seen from the following example:

**21 Example.** Let  $X$  be an uncountable set and let  $T$  be the cocountable topology on  $X$ . Then  $(X, T)$  is  $\beta$ -US but not  $\beta$ - $T_2$ . The above example also shows that a US-space need not be  $\beta$ - $T_2$ .

**22 Definition.** A set  $B$  is said to be sequentially  $\beta$ -closed if every sequence in  $B$   $\beta$ -converges to a point in  $B$ .

**23 Theorem.** *A space  $X$  is  $\beta$ -US if and only if the diagonal  $\Delta$  is a sequentially  $\beta$ -closed subset of  $X \times X$ .*

PROOF. Let  $X$  be  $\beta$ -US. Let  $\langle x_n, x_n \rangle$  be a sequence in  $\Delta$ . Suppose that  $\langle x_n, x_n \rangle$   $\beta$ -converges to  $\langle x, y \rangle$ . That is,  $\langle x_n \rangle$   $\beta$ -converges to  $x$  and  $y$ . Therefore  $x = y$ . Hence  $\Delta$  is sequentially  $\beta$ -closed. Conversely, let  $\Delta$  be sequentially  $\beta$ -closed. Let a sequence  $\langle x_n \rangle$   $\beta$ -converges to  $x$  and  $y$ . Hence,  $\langle x_n, x_n \rangle$   $\beta$ -converges to  $\langle x, y \rangle$ . Since  $\Delta$  is sequentially  $\beta$ -closed,  $\langle x, y \rangle \in \Delta$ , which means that  $x = y$ .  $\square$

**24 Definition.** A subset  $Y$  of a space  $X$  is said to be sequentially  $\beta$ -compact if every sequence in  $Y$  has a subsequence which  $\beta$ -converges to a point in  $Y$ .

**25 Theorem.** *In a  $\beta$ -US space, every sequentially  $\beta$ -compact set is sequentially  $\beta$ -closed.*

PROOF. Let  $X$  be  $\beta$ -US. Let  $Y$  be a sequentially  $\beta$ -compact subset of  $X$ . Let  $\langle x_n \rangle$  be a sequence in  $Y$ . Suppose that  $\langle x_n \rangle$   $\beta$ -converges to a point in  $X \sim Y$ . Let  $\langle x_{np} \rangle$  be a subsequence of  $\langle x_n \rangle$ . Since  $Y$  is sequentially  $\beta$ -compact, there exists a subsequence  $\langle x_{np} \rangle$  of  $\langle x_n \rangle$  such that  $\langle x_{np} \rangle$   $\beta$ -converges to a point  $y$  in  $Y$ . Also, a subsequence of  $\langle x_n \rangle, \langle x_{np} \rangle$   $\beta$ -converges to  $x \in X \sim Y$ . Since  $\langle x_{np} \rangle$  is a sequence in  $\beta$ -US space  $X, x = y$ . Thus,  $Y$  is sequentially  $\beta$ -closed. □ QED

**26 Theorem.** *Product of arbitrary family of  $\beta$ -US spaces is  $\beta$ -US.*

PROOF. Let  $X = \prod_{\lambda \in \Delta} X_\lambda$  where each  $X_\lambda$  is  $\beta$ -US. Let a sequence  $\langle x_n \rangle$  in  $X$   $\beta$ -converges to  $x = (x_\lambda)$  and  $y = (y_\lambda)$ . Then the sequence  $\langle x_{n\lambda} \rangle$   $\beta$ -converges to  $x_\lambda$  and  $y_\lambda$  for each  $\lambda \in \Delta$ . For, suppose that there exists a  $\mu \in \Delta$  such that  $\langle x_{n\mu} \rangle$  does not  $\beta$ -converge to  $x_\mu$ . Then there exists a  $\tau_\mu$ - $\beta$ -open set  $U_\mu$  containing  $x_\mu$  such that  $\langle x_{n\mu} \rangle$  is not eventually in  $U_\mu$ . Consider the set  $U = \prod_{\lambda \neq \mu} X_\lambda \times U_\mu$ . Then  $U$  is a  $\beta$ -open subset of  $X$  [2, Lemma 2.1] and  $\langle x_n \rangle$  is not eventually in  $U$  which contradicts the fact that  $\langle x_n \rangle$   $\beta$ -converges to  $x$ . Thus we get  $\langle x_{n\lambda} \rangle$   $\beta$ -converges to  $x_\lambda$  and  $y_\lambda$  for each  $\lambda \in \Delta$ . Since  $X_\lambda$  is  $\beta$ -US,  $x_\lambda = y_\lambda$  for each  $\lambda \in \Delta$ . Thus  $x = y$ . Hence,  $X$  is  $\beta$ -US. □ QED

**27 Corollary.** *Product of arbitrary family of  $\beta$ - $T_2$  space is  $\beta$ - $T_2$ .*

**28 Theorem.** *Every  $\alpha$ -open-subset of  $\beta$ -US space is  $\beta$ -US.*

PROOF. Let  $Y \subseteq X$  be an  $\alpha$ -open set. Let  $\langle x_n \rangle$  be a sequence in  $Y$ . Suppose that  $\langle x_n \rangle$   $\beta$ -converges to  $x$  and  $y$  in  $Y$ . We shall prove that  $\langle x_n \rangle$   $\beta$ -converges to  $x$  and  $y$  in  $X$ . Let  $U$  be any  $\beta$ -open subset of  $X$  containing  $x$  and  $V$  be any  $\beta$ -open subset of  $X$  containing  $y$ . Then  $U \cap Y$  and  $V \cap Y$  are  $\beta$ -open subsets of  $Y$  [1, Lemma 2.5]. Therefore  $\langle x_n \rangle$  is eventually in  $U \cap Y$  and  $V \cap Y$  and hence in  $U$  and  $V$ . Since  $X$  is  $\beta$ -US,  $x = y$ . Hence  $Y$  is  $\beta$ -US. □ QED

**29 Corollary.** *Every  $\alpha$ -open-subset of  $\beta$ - $T_2$  space is  $\beta$ - $T_2$ .*

**30 Remark.** The subset  $\{a, c\}$  considered in Example 6 is not  $\beta$ - $T_2$ . This shows that an arbitrary subset of  $\beta$ - $T_2$  space need not be  $\beta$ - $T_2$ .

## 4 Some functions

**31 Theorem.** *The image of a  $\beta$ -US space under a bijective pre- $\beta$ -closed function is  $\beta$ -US.*

PROOF. Let  $f: X \rightarrow Y$  be a bijective and pre- $\beta$ -closed function and let  $X$  be  $\beta$ -US. Let  $\langle y_n \rangle$  be a sequence in  $Y$ . Suppose that  $\langle y_n \rangle$   $\beta$ -converges to two points  $y_1$  and  $y_2$ . In that case we shall prove that the sequence  $\langle f^{-1}(y_n) \rangle$   $\beta$ -converges to  $f^{-1}(y_1)$  and  $f^{-1}(y_2)$ . Let  $U$  be a  $\beta$ -open set containing  $f^{-1}(y_1)$ . Then  $f(U)$  is a  $\beta$ -open set containing  $y_1$  and hence  $\langle y_n \rangle$  is eventually in  $f(U)$ . Therefore

$\langle f^{-1}(y_n) \rangle$  is eventually in  $U$ . Hence  $\langle f^{-1}(y_n) \rangle$   $\beta$ -converges to  $f^{-1}(y_1)$ . Similarly we can prove that  $\langle f^{-1}(y_n) \rangle$   $\beta$ -converges to  $f^{-1}(y_2)$ . This is not possible since  $X$  is  $\beta$ -US. Hence  $Y$  is  $\beta$ -US.  $\square$

**32 Corollary.** *The image of a  $\beta$ - $T_2$  space under a bijective pre- $\beta$ -closed function is  $\beta$ - $T_2$ .*

**33 Definition.** A function  $f: X \rightarrow Y$  is said to be totally  $\beta$ -continuous if the inverse image of every open subset of  $Y$  is a  $\beta$ -clopen subset of  $X$ .

**34 Theorem.** *A space  $X$  is  $\beta$ - $T_2$  if for any two distinct points  $x$  and  $y$  of  $X$ , there exist  $\beta$ -open sets  $U$  and  $V$  such  $x \in U, y \in V$  and  $\beta \text{Cl}(U) \cap \beta \text{Cl}(V) = \emptyset$ .*

PROOF. It is Lemma 2.3 of [14].  $\square$

**35 Lemma.** *Let  $f: X \rightarrow Y$  be a totally  $\beta$ -continuous injection. If  $Y$  is  $T_0$ , then  $X$  is  $\beta$ - $T_2$ .*

PROOF. Let  $a$  and  $b$  be any pair of distinct points of  $X$ . Then  $f(a) \neq f(b)$ . Since  $Y$  is  $T_0$ , there exists an open set  $U$  containing  $f(a)$  but not  $f(b)$ . Then  $a \in f^{-1}(U)$  and  $b \notin f^{-1}(U)$ . As  $f$  is totally  $\beta$ -continuous,  $f^{-1}(U)$  is a  $\beta$ -clopen subset of  $X$ . Also  $a \in f^{-1}(U)$  and  $b \in X \setminus f^{-1}(U)$ . By Theorem 34,  $X$  is  $\beta$ - $T_2$ .  $\square$

**36 Theorem.** *Let  $f: X \rightarrow Y$  be a totally  $\beta$ -continuous injection. If  $Y$  is  $T_0$ , then  $X$  is  $\beta$ -US.*

PROOF. Immediate in view of Theorem 20 and Lemma 35.  $\square$

**37 Definition.** A function  $f: X \rightarrow Y$  is said to be

- (i) *Sequentially  $\beta$ -continuous* at  $x \in X$  if  $f(x_n)$   $\beta$ -converges to  $f(x)$  whenever  $x_n$  is a sequence  $\beta$ -converges to  $x$ . If  $f$  is sequentially  $\beta$ -continuous for all  $x$  in  $X$ , then  $f$  is sequentially  $\beta$ -continuous.
- (ii) *Sequentially nearly  $\beta$ -continuous* if for each  $x$  in  $X$  and each sequence  $x_n$  in  $X$   $\beta$ -converging to  $x$ , there exists a subsequence  $x_{nk}$  of  $x_n$  such that  $f(x_{nk})^\beta \rightarrow f(x)$
- (iii) *Sequentially sub  $\beta$ -continuous* if for each  $x$  in  $X$  and each sequence  $x_n$  in  $X$   $\beta$ -converging to  $x$ , there exists a subsequence  $x_{nk}$  of  $x_n$  and a point  $y$  in  $Y$  such that  $f(x_{nk})^\beta \rightarrow y$ .
- (iv) *Sequentially  $\beta$ -compact preserving* if the image  $f(C)$  of every sequentially  $\beta$ -compact set  $C$  of  $X$  is sequentially  $\beta$ -compact set in  $Y$ .

**38 Theorem.** *Let  $f: X \rightarrow Y$  and  $g: X \rightarrow Y$  be two sequentially  $\beta$ -continuous functions. If  $Y$  is  $\beta$ -US, then the set  $E = \{x \mid f(x) = g(x)\}$  is sequentially  $\beta$ -closed.*

PROOF. Suppose that  $Y$  is  $\beta$ -US and  $\langle x_n \rangle$  is a sequence in  $E$   $\beta$ -converging to  $x$  in  $X$ . By hypothesis  $f$  and  $g$  are sequentially  $\beta$ -continuous functions, so  $f(x_n)^\beta \rightarrow f(x)$  and  $g(x_n)^\beta \rightarrow g(x)$ . Since  $x_n \in E$  for each  $n$  and  $Y$  is  $\beta$ -US,  $f(x) = g(x)$  and hence  $x \in E$ . This shows that the set  $E$  is sequentially  $\beta$ -closed.  $\square$

**39 Lemma.** *Every function  $f: X \rightarrow Y$  is sequentially sub  $\beta$ -continuous if  $Y$  is sequentially  $\beta$ -compact.*

PROOF. Assume that  $\langle x_n \rangle$  is a sequence in  $X$   $\beta$ -converging to  $x$  in  $X$ . It follows that  $\{f(x_n)\}$  is a sequence in  $Y$ . Since  $Y$  is sequentially  $\beta$ -compact, there exists a subsequence  $\{f(x_{nk})\}$  of  $\{f(x_n)\}$   $\beta$ -converging to a point  $y$  in  $Y$ . Therefore  $f: X \rightarrow Y$  is sequentially sub  $\beta$ -continuous.  $\square$

**40 Theorem.** *Every sequentially nearly  $\beta$ -continuous function is sequentially  $\beta$ -compact preserving.*

PROOF. Let  $f: X \rightarrow Y$  be a sequentially nearly  $\beta$ -continuous function and  $C$  be any sequentially  $\beta$ -compact subset of  $X$ . We show that  $f(C)$  is a sequentially  $\beta$ -compact set of  $Y$ . Assume that  $\langle y_n \rangle$  be any sequence in  $f(C)$ . Then for each positive integer  $n$ , there exist a point  $x_n$  in  $C$  such that  $f(x_n) = y_n$ . Now  $\langle x_n \rangle$  is a sequence in a sequentially  $\beta$ -compact set  $C$ . Thus there exists a subsequence  $\langle x_{nk} \rangle$  of  $\langle x_n \rangle$   $\beta$ -converging to a point  $x$  in  $C$ . Since  $f$  is sequentially nearly  $\beta$ -continuous, there exists a subsequence  $\langle x_j \rangle$  of  $\langle x_{nk} \rangle$  such that  $f(x_j)^\beta \rightarrow f(x)$ . So there exists a subsequence  $\langle y_i \rangle$  of  $\langle y_n \rangle$   $\beta$ -converging to  $f(x)$  in  $f(C)$ . This implies that  $f(C)$  is a sequentially  $\beta$ -compact set of  $Y$ .  $\square$

**41 Theorem.** *Every sequentially  $\beta$ -compact preserving function is sequentially sub  $\beta$ -continuous.*

PROOF. Suppose that  $f: X \rightarrow Y$  is a sequentially  $\beta$ -compact preserving function. Let  $x$  be any point of  $X$  and  $x_n$  be any sequence in  $X$   $\beta$ -converging to  $x$ . We denote the set  $\{x_n \mid n = 1, 2, \dots\}$  by  $A$  and put  $K = A \cup \{x\}$ . Since  $x_n$   $\beta$ -converges to  $x$ ,  $K$  is sequentially  $\beta$ -compact, by hypothesis,  $f$  is sequentially  $\beta$ -compact preserving and hence  $f(K)$  is a sequentially  $\beta$ -compact set of  $Y$ . Since  $\{f(x_n)\}$  is a sequence in  $f(K)$ , there exists a subsequence  $\{f(x_{nk})\}$  of  $\{f(x_n)\}$   $\beta$ -converging to a point  $y \in f(K)$ . This implies that  $f$  is sequentially sub  $\beta$ -continuous.  $\square$

**42 Theorem.** *A function  $f: X \rightarrow Y$  is a sequentially  $\beta$ -compact preserving function if and only if  $f \mid K: K \rightarrow f(K)$  is sequentially sub  $\beta$ -continuous for each sequentially  $\beta$ -compact subset  $K$  of  $X$ .*

PROOF. Necessity. Suppose that  $f: X \rightarrow Y$  is a sequentially  $\beta$ -compact preserving function. Then  $f(K)$  is sequentially  $\beta$ -compact in  $Y$  for each sequentially  $\beta$ -compact set  $K$  of  $X$ . Therefore by Lemma 39,  $f \mid K: K \rightarrow f(K)$  is sequentially sub  $\beta$ -continuous.

Sufficiency. Let  $K$  be any sequentially  $\beta$ -compact set of  $X$ , we show that  $f(K)$  is sequentially  $\beta$ -compact in  $Y$ . Let  $y_n$  be any sequence in  $f(K)$ . Then for each positive integer  $n$ , there exists a point  $x_n \in K$  such that  $f(x_n) = y_n$ . Since  $\langle x_n \rangle$  is a sequence in a sequentially  $\beta$ -compact set  $K$ , there exists a subsequence  $\langle x_{nk} \rangle$  of  $\langle x_n \rangle$   $\beta$ -converging to a point  $x \in K$ . By hypothesis,  $f \upharpoonright K: K \rightarrow f(K)$  is sequentially sub  $\beta$ -continuous and hence there exists a subsequence of the sequence  $\langle y_{nk} \rangle$   $\beta$ -converging to  $y \in f(K)$ . This implies that  $f(K)$  is sequentially  $\beta$ -compact in  $Y$ . Thus,  $f: X \rightarrow Y$  is sequentially  $\beta$ -compact preserving.  $\square$   $\overline{QED}$

**Acknowledgements.** The author is deeply grateful to Dr. Arya for her valuable suggestions and remarks. Also author conveys his heartfelt thanks to the referee for his guidance that improved the quality of the paper.
